

Disadvantages of tapered beam splitters

Overview

Beamsplitters are generally effective at reflecting s-polarization but they are not as effective at preventing p-polarization from reflecting. This occurs because when s-polarized light hits the reflecting surface, the electric field is in the same plane as the surface. Beamsplitters are often classified according to their construction: cube or plate. Arrangements of mirrors or prisms used as camera attachments to photograph stereoscopic image pairs with one lens and one exposure are sometimes called "beam splitters", but that is a misnomer, as they are effectively a pair of periscopes redirecting rays of light which are already non-coincident. A beam splitter (or beamsplitter, power splitter) is an optical device which can split an incident light beam (e. a laser beam) into two (or sometimes more) beams, which may or may not have the same optical power (radiant flux). Equal splitter ratios for all branches.

In its most common form, a cube, a beam splitter is made from two triangular glass prisms which are glued together at their base using polyester, epoxy, or urethane-based adhesives. (Before these synthetic resins, natural ones were used, e.g. Canada balsam.) The thickness of the resin layer is adjusted such that (for a certain wavelength) half of the light incident through one "port" (i.e., face of the cube) is reflected and th
