

Main power distribution box to sub-distribution box trunk line

Overview

For power transmission between the transformer and the low voltage switchboard, or from the main distribution board to the sub distribution board, trunking units of a busbar trunking system without tap off points are used. Primary distribution systems consist of feeders that deliver power from distribution substations to distribution transformers. At this. The electricity supply chain consists of three primary segments: generation, where electricity is produced; transmission, which moves power over long distances via high-voltage power lines; and distribution, which moves power over shorter distances to end users (homes, businesses, industrial sites. When a high level of flexibility is requested for transmission, distribution, switching, and protection of electrical energy with, at the same time, low space requirements and a high reliability, the busbar trunking systems are the innovative alternative to conventional cable installations. And all the switching and protective devices are installed in the distribution box. A feeder can connect two substation buses in parallel to ensure stable power and continuous service for the loads from each bus.
